Table of Contents

- Cover and Preface
- Organization and Committees
- Sponsors and Organizers

Part I: 4th International Workshop on Professional Retraining and Life-Long Learning using ICT: Person-oriented Approach (3L-Person 2019)

- About One Approach to Building Systems for Testing Physical Knowledge1-16
 Michail Lvov, Sergiy Kuzmenkov, Hennadiy Kravtsov
- Increase of the Level of Graphic Competence Future Bachelor in Computer Sciences in the Process of Studying 3D Modeling17-28 Hanna Chemerys, Kateryna Osadcha, Viacheslav Osadchyi, Vladyslav Kruhlyk
- Ontological Model of Representation of University Resources29-40
 Bogdan Buyak, Ivan Tsidylo, Serhiy Kozibroda, Victor Repskyi
- Mathematical Models and Methods of Supporting the Solution of the Geometry Tasks In Systems of Computer Mathematics for

- Educational Purposes41-52 Michael Lvov, Ludmila Shishko, Irina Chernenko, Evgen Kozlovsky
- Attitude to the Digital Learning Environment in Ukrainian Universities53-67
 Olong Kuzmineke, Marija Mazarabuk, Natalija Mazarabuk, Natalija
 - Olena Kuzminska, Mariia Mazorchuk, Nataliia Morze, Oleg Kobylin
- The blended Methodology of Learning Computer Networks: Cloud-based Approach68-80
 Oleg Spirin, Vasyl Oleksiuk, Nadiia Balyk, Svitlana Lytvynova, Sergiy Sydorenko
- The Method of Using the Maxima System for Operations Research Learning81-92
 Mariya Shyshkina, Uliana Kohut
- The Comparative Analysis of the Cloud-based Learning Components Delivering Access to Mathematical Software93-104
 Mariya Shyshkina, Uliana Kohut, Maiia Popel
- Electronic Textbook as a Component of Smart Kids Technology of Education of Elementary School Pupils105-120
 Svitlana Lytvynova
- Technologies of Virtual and Augmented Reality for High Education and Secondary School121-131
 Nataliia Osipova, Hennadiy Kravtsov, Olga Gnedkova, Tetiana Lishchuk, Kateryna Davidenko
- Activity Plan Template for Supporting Study Science with Robotics and Programming132-143
 Tatiana Goncharenko, Nataliya Kushnir, Nataliia Valko, Nataliya Osipova
- Determining the Level of Readiness of Teachers to Implementation of STEM-Education in Ukraine144-155
 Viacheslav Osadchyi, Nataliia Valko, Nataliya Kushnir
- Open Distance Learning For Teachers156-169
 Vladimir Kukharenko, Tatyana Oleinik
- The Technique to Evaluate Pupils' Intellectual and Personal Important Qualities for ICT Competences170-177
 Svitlana Lytvynova, Oleksandr Burov, Olga Slobodyanyk
- The Method for Forming the Health-Saving Component of Basic School Students' Digital Competence178-190
 Yuliya Nosenko, Alisa Sukhikh
- ICT in Professional Education of Future Primary School Teachers: Modeling of Scientific and Research Work191-203

- Yevheniia Spivakovska, Tetyana Vinnyk, Liudmula Perminova, Vera Kotkova
- Design of Approaches to the Development of Teacher's Digital Competencies in the Process of Their Lifelong Learning204-219 Nadiia Balyk, Yaroslav Vasylenko, Galina Shmyger, Vasyl Oleksiuk, Anna Skaskiv
- Information System of Scientific Activity Indicators of Scientific Organizations: Development Status and Prospects220-228
 Aleksandr Spivakovsky, Maksym Vinnik, Maksym Poltoratskiy, Yulia Tarasich, Yevheniia Spivakovska, Greg Gardner, Kateryna Panova
- Advanced Information Technology Tools for Media and Information Literacy Training229-240
 Yuliya Krylova-Grek

Part II: 7th International Workshop on Information Technologies in Economic Research (ITER 2019)

- Information-Analytical Support for the Processes of Formation of "Smart Sociopolis" of Truskavets241-256
 Mykola Odrekhivskyy, Nataliia Kunanets, Volodymyr Pasichnyk, Antonii Rzheuskyi, Danylo Tabachyshyn
- The Main Aspects of the Introduction of ERP-Systems at the Machine-Building Enterprises257-268
 Irina Nyzhnyk, Viktor Lysak
- Business Models of Reproduction Cycles for Digital Economy269-276
 Leonid Melnyk, Oleksandr Derykolenko, Oleksandr
 Kubatko, Oleksandr Matsenko
- Support of Investors' Decision Making in Economic Experiments Using Software Tools277-288
 Daria Kilinich, Vitaliy Kobets
- Application of Geographic Information Systems in the Field of Domestic Waste Management289-301
 Olga Popova, Liubov Pankratova, Inesa Mikhno
- Forecasting of Cereal Crop Harvest on the Basis of an Extrapolation Canonical Model of a Vector Random Sequence302-315
 Igor Atamanyuk, Yuriy Kondratenko, Anastasiya Poltorak, Natalia Sirenko, Vyacheslav Shebanin, Inna Baryshevska, Valeriia Atamaniuk
- Cloud Based Architecture of the Core Banking System316-331
 Andrii Roskladka, Nataliia Roskladka, Ganna Kharlamova, Roman Baglai

 Forecasting Prices on the Stock Exchange Using a Trading System332-347
 Liubov Pankratova, Tetiana Paientko, Yaroslav Lysenko

 The Relationship between Oil and Gas Prices, Dow Jones and US Dollar Indexes: A Wavelet Co-movement Estimation and Neural Network Forecasting348-363
 Olena Liashenko, Tetyana Kravets

 Short-term Electricity Price Forecasting Using Generalized Additive Models364-378
 Jan-Hendrik Meier, Stephan Schneider, Chan Le

 Budgeting Integration with a Business Strategy and Accounting System in Business Process Management - Case Study of Ukrainian Company379-392
 Viktoria Yatsenko, Yevhen Kudriavets

 Can Information Technology Increase Government Effectiveness?393-405
 Tetiana Paientko, Viktor Fedosov

 Cluster Analysis of Countries Inequality due to IT Development406-421
 Vitaliy Kobets, Valeria Yatsenko, Mykhaylo Voynarenko

- Simplified Model of Bank Balance Sheet Management422-433
 Victor Selyutin
- Entropy Analysis of Crisis Phenomena for DJIA Index434-449
 Vladimir Soloviev, Andrii Bielinskyi, Viktoria Solovieva
- Influence of the Country's Information Development on its Tourist Attractiveness450-464
 Yuliia Lola, Svitlana Prokopovych, Olena Akhmedova
- Empowering Fault-Tolerant Consensus Algorithm by Economic Leverages465-472
 Igor Mazurok, Valeriy Pienko, Yevhen Leonchyk
- Government Financial Support of Higher Education and its Role in Economic Prosperity of a Society473-484
 Marina Bilinets, Lidiia Hladchenko, Tetiana Paientko
- Simulation of the Crisis Contagion Process Between Countries with Different Levels of Socio-Economic Development485-496
 Andriy Matviychuk, Inna Strelchenko, Serhii Vashchaiev, Halyna Velykoivanenko

Part III: 3nd International Workshop on Rigorous Methods in Software Engineering (RMSE 2019)

- Computations in Extensions of Multisorted Algebras 497-512
 Michael Lvov
- On Some Classes of Problems on Graphs513-521
 Volodymyr G. Skobelev
- Extending the SMT-Lib Standard with Theory of Nominative Data522-533
 - Liudmyla Omelchuk, Olena Shyshatska
- Data Compression and Representation as Multicolor Barcodes534-541
 - Ivan Dychka, Olga Sulema
- On the Kleene Algebra of Partial Predicates with Predicate Complement542-551
 Ievgen Ivanov, Mykola Nikitchenko
- Computational Modeling and Structural Stability552-567
 Alexander Weissblut
- Event Universes: Specification and Analysis Using Coq Proof Assistant568-576
 Grygoriy Zholtkevych
- Formalization and Algebraic Modeling of Tokenomics Projects577-584
 Oleksandr Letychevskyi, Volodymyr Peschanenko, Viktor
 Radchenko, Maksym Poltoratskyi, Yuliia Tarasich
- Formalization and Algebraic Modeling of University Economics585-594
 - Volodymyr Peschanenko, Maksym Poltoratskyi, Karina Pryimak
- Formalization of the Model of Management of the Technological Innovations595-602
 Vitalina Babenko
- Program Logics of Renominative Level with the Composition of Predicate Complement603-616
 Mykola Nikitchenko, Oksana Shkilniak, Stepan Shkilniak

Part IV: 5th International Workshop on Theory of Reliability and Markov Modeling for Information Technologies (TheRMIT 2019)

- Agent-Oriented Information Technology for Assessing the Initial Stages of the Software Life Cycle617-632
 Tetiana Hovorushchenko, Artem Boyarchuk, Olga Pavlova, Kira Bobrovnikova
- Dynamic Signature-based Malware Detection Technique Based on API Call Tracing633-643
 Oleg Savenko, Andrii Nicheporuk, Ivan Hurman, Sergii Lysenko

- On-Line Checking of Faults in Cyber-Physical Systems644-654
 Volodymyr G. Skobelev, Volodymyr V. Skobelev
- Ensuring the Security of the Full Logistics Supply Chain Based on the Blockchain Technology655-663
 Igor Shostak, Yashar Rahimi, Mariia Danova, Olena Feoktystova, Olga Melnyk
- Application of the Booking.com Analytics Software Tools in Reliable Processing of Big Data in Hotels Management664-677
 Vladimir Sklyar, Vyacheslav Kharchenko

Computational Modeling and Structural Stability

Alexander Weissblut1[0000-0002-1476-8884]

¹Kherson State University, 27, Universitetska st., Kherson, 73000 Ukraine veitsblit@gmail.com

Abstract. The structural stability of a mathematical model with respect to small changes is a necessary condition for its correctness. The same condition is also necessary for the applicability of numerical methods, a computational experiment. But after S. Smale's works it became clear that in smooth dynamics the system of a general form is not structurally stable, therefore there is no strict mathematical basis for modeling and computational analysis of systems. The contradiction appeared in science: according to physicists dynamics is simple and universal. The paper proposes a solution to this problem based on the construction of dynamic quantum models (DQM). DQM is a perturbation of a smooth dynamical system by a Markov cascade (time is discrete). The dynamics obtained in this way are simpler than smooth dynamics: the structurally stable DQM realizations are everywhere dense and open on the set of all DQM realizations. This dynamics in contrast to the classical one has a clear structural theory, which makes it possible to construct effective algorithms for study of concrete systems. For example this paper shows the use of computer simulation for rigorous proof of hyperbolicity of the Henon system attractor. On the other hand, when fluctuations tend to zero, i.e. in the semiclassical limit, the dynamics of the DQM goes into the initial smooth dynamics. In this paper the equivalence of structural stability and hyperbolicity for smooth discrete dynamical systems is established along this path.

Keywords: modeling, computer simulation, structural stability, dynamical system, dynamic quantum model, Markov cascade, attractor.

1 Introduction

Computational modeling derives from two steps: (i) modeling, i.e. finding a model description of a real system, and (ii) solving the resulting model equations using computational methods [1]. Computational modeling has been used in physics, chemistry and related engineering for many decades because in practice hardly any model equations of systems of interest can be solved analytically, and this is where the computer comes in [2].

However, if an arbitrarily small perturbation of the model leads to a qualitatively different picture of the dynamics, then such a model is not applicable to the real process: strictly speaking, perturbations are included in the definition of a model. Therefore traditionally the stability of a mathematical model with respect to relatively small changes is a necessary condition for its correctness [3]. The same stability condition is

necessary for applicability of numerical methods, computational experiments since they inevitably lead to errors of discretization and rounding in calculations [4].

The qualitative invariance of a mathematical model under small perturbations is usually called structural stability. This formally means equivalence, in some exact sense, between the model and its small enough perturbation. For the smooth dynamical systems (sets of differential or difference equations) this equivalence is usually a homeomorphism between the phase portraits of these systems. Such theory of a structural stability going back to H. Poincare, has been developed by A.Andronov and L. Pontrjagin in the case of small dimension of the phase space (1 or 2) [5]. However, the optimism generated by the successes of this theory disappeared after S. Smale's works [6]. It was shown in [7] that when the phase space has larger dimension, then there exist smooth dynamic systems whose neighborhoods do not contain any structurally stable system. For the theory of smooth dynamical systems (its old name is the qualitative theory of differential equations) this result has the same value as Liouville's theorem on insolvability of the differential equations in quadratures has for the theory of their integration. Namely, it shows that the problem of full topological classification of smooth dynamical systems is hopeless. This means also that there is no strict mathematical basis for modeling and computational analysis. The contradiction has appeared in science, because physicists believe that the dynamics is simple and universal [8].

The paper proposes solution to this problem, based on the construction of dynamic quantum models (DQM). It turns out that taking into account random fluctuations, necessary for the transition to the quantum model of reality, allows us to return in fact to the simple picture of A. Poincare's dynamics: a dense set of structurally stable systems.

DQM is so named because for Hamiltonian systems it is simply related to the corresponding Schrödinger equation, and its construction is the basis of the method for solving spectral problems [9]. But the definition of DQM is not formally related to Hamiltonian systems; it is defined for any ordinary differential equation or any diffeomorphism on any smooth Riemannian manifold.

The structural stability of the general form DQM opens the way to a mathematically grounded numerical analysis of the dynamics. As an example, this paper shows the use of computer simulation for rigorous proof of hyperbolicity of the Henon system attractor [10] at certain values of parameters. DQM is the natural basis for solving the traditional problems of machine learning [11].

On the other hand, when fluctuations tend to zero, i.e. in the semiclassical limit, the dynamics of the DQM goes into a more complex initial smooth dynamics. The old problem – the equivalence of structural stability and hyperbolicity for smooth discrete dynamical systems [12] is established by this way in this paper.

The **paper goal** is 1) to build the foundations of the theory of dynamic quantum models (DQM); 2) to demonstrate the application of this theory for computer research of concrete systems and for solving traditional problems of the theory of smooth dynamical systems.

The paper is organized as follows: in part 2 we synthesize the dynamic quantum models (DQM), in section 2.2 we define the DQM attractor, show the uniqueness of this definition and establish properties of the DQM attractor; in part 3 we show that structurally stable realizations of DQM are dense and open on the set of all its

realizations; in part 4 we demonstrate the use of computer modeling for rigorous proof of hyperbolicity of the attractor of Henon system; part 5 concludes.

We had to omit proofs of some theorems in order to fit the paper format.

2 The Dynamic Quantum Model: Basic Definitions

2.1 DQM Definition

Let p(x) be an n-dimensional smooth vector field on an n-dimensional smooth Riemannian manifold M, where $x(x_1, x_2, ..., x_n)$ are local Euclidean coordinates on M, p(x) $C(R^n)$ (i=1,...,n). On each phase curve x(t) M of the dynamical system generated by this vector field

$$\frac{dx_i}{dt}p_i(x), \quad (i \quad 1,...,n)$$
 (1)

consider the integral of the "shortened action" $s(t) = p(x)dx = \int\limits_{x(t)}^{t} |p(\cdot)||^2 d$,

where $p(\cdot)^{2} \int_{t=1}^{n} p_{t}^{2}(\cdot)$. The value of s(t) on each curve x(t), which is different

from a fixed point, is diffeomorphically expressed in t and is called "optical time".

Let be a metric such that
$$s(t)$$
 d : d $p(t)$ d d . The following is the heuristic

derivation or explanation of the definition of dynamic quantum model (Definition 1). So, the distance d traveled by a point along the path of (1) during the time t is

equal to
$$d = p(t_c) d = p(t_c) t$$
 , where $p_c = p(t_0)$ is the average value

 $(0\ t_0\ t)$. (Of course this is with a single bypass of trajectory during t: turning points are the special case). Further, we assume that the fluctuations generate "white

acting on the configuration space with the dispersion
$$D \ (t)$$

where the diffusion coefficient 2 is constant over the considered time interval. It will take some time t, until the point moves to a distance d from the initial position, which exceeds the mean square error caused by (t) during the time t, i.e. $p_c \mid t$

will exceed
$$\sqrt{\frac{2}{t}}$$
 t . With such a minimal t p_c t = \sqrt{t} , whence p_c

$$\Delta = \frac{2}{\|\Delta\|}, \quad = \| \|\Delta\| = \frac{2}{\|\Delta\|} \tag{2}$$

Here by assumption t is the minimal time interval after which it becomes possible to make a new measurement, the difference from which will exceed the error, i.e. get a significantly different measurement. Owing to (2) $p_c \begin{vmatrix} 2 & t \end{vmatrix} p() \begin{vmatrix} 2 & d & s(t) \end{vmatrix}$.

Thus 1) the time interval between the

nearest significant measurements is unchanged on the optical time scale and is equal to 2 . (In other words, the distance between them in the metric is equal to 2). 2) During this time "white noise" (t) generates an irremovable random error, the standard deviation of which is equal to the distance d between the nearest significant measurements along the trajectory.

So, a dynamic quantum model first shifts each point along the phase curve of a given dynamic system over the optical time 2 (or ρ – length 2), and then randomly shifts on a distance not exceeding the length of the trajectory from the original to the new point. The following rigorous definition summarizes this description. The definition of a dynamic quantum model is given for an arbitrary dynamic system (1) on an arbitrary compact Riemannian manifold M.

Let G be the shift map along the phase trajectories of (1) during the lag time t. Consider a smooth function q(y, z) 0 (y, z M) such that

where $d\left(y\right)$ 0 is a continuous function on M. Here $q\left(y,z\right)$ defines the density of "local random dissipation caused by white noise," the numbers $d\left(y\right)$ are assumed to be small. Of course, the function $q\left(y,z\right)$ can also be assumed continuous, approximating it on M with a smooth function for any given accuracy. Then **Definition 1.** The Markov process with the transition function

$$P(y,A)q(y,z)dz (A M)$$
 (4)

is called the dynamic quantum model (DQM) for the dynamic system (1). Given the initial distribution, we obtain a Markov process P with this initial distribution and the transition function $P(\ y,A)$: if t is the distribution at time t, t is the lag between the two nearest measurements, then the DQM sets new distribution $P(\ t\)$ t at time t t.

Thus, based on the differential equations (1), we arrive at difference equations with a lag of at least 2 on the optical time scale. At first glance, the DQM may surprise with the discreteness of time: in the traditional model of quantum mechanics errors are explicitly taken into account only for spatial variables. But, as can be seen from the deduction, the discreteness of the measurement process is an inevitable consequence of the unavoidable errors of coordinates and pulses. Indeed, to measure time ultimately requires a clock or other device in which readings on a scale are measured in proportion to time at a certain speed. But if these readings and speed are determined inaccurately, then the time is also known only with some error.

Definition 2. Let i be cells with a diameter of some partition of the phase space of a dynamical system and 0 is the initial state. Then the Markov chain with transition probabilities from i to j equal to $p_{ij} = \underbrace{1}_{0} P(y, j) d_0$ will be called

the $\,$ - discretization of DQM with transition function $\,P(\,y,A)$ and initial state $\,$ $\,$ $\,$ $\,$ $\,$

2.2 DQM Attractor

Attractor is the key concept of the theory of dynamical systems; its physical meaning is that it is "the space of steady-state regimes". The point of the phase space is contained in the attractor if it belongs to the carrier of the "stationary state of the system", i.e. to a measure not changing over time.

Let M be a compact phase space, P is some DQM on M .

Definition 3. The probability measure on M will be called the stationary (equilibrium) state of DQM if $P(\)$. The DQM attractor is the union of the carriers of all stationary states.

Theorem 1. (Perron-Frobenius theorem for DQM). Let M be an invariant closed set of DQM P that does not contain its own invariant closed subsets (that is minimal with respect to P). Then

- 1. there is a unique stationary state, whose carrier is. The state is ergodic (that is the flow P is ergodic with respect to measure).
- 2. For any other state (probability measure) onlim $\frac{1}{n} P_k^n = .$
- 3. If is a probabilistic stationary measure of some $\,$ discretization of the given DQM onthen $\underset{0}{lim} \equiv \,$.

Proof. Let M be an invariant closed set of DQM that does not contain its own invariant closed subsets. Let \overline{b} e a stationary measure of some discretization of the given DQM on with cells of diameter (that is, a probability invariant measure of a Markov chain defined by Definition 3). On a compact subset of the phase space

weak topology. Therefore in any sequence of measures $_k$ one can find a subsequence—, converging to some measure—from $R:\lim_{n}=R$ in the sense of the weak topology on R. Since P=00 (in the sense of the weak topology) by virtue of definition 3, then P=01 i.e.—is a stationary state of DQM. Since by the condition—does not contain non-empty proper invariant subsets of DQM (i.e. it is metrically transitive), then for any P-invariant measure on—the ergodic Neumann theorem holds: for any continuous function—P0 on—P1.

$$L^2 \quad \lim_{n} \frac{1}{n} \int_{-\infty}^{n} f(P^k) \qquad fd$$
 (5)

Obviously, there are only finitely many components of the DQM attractor k on M, that is such invariant subsets of the attractor that do not contain proper invariant non-empty subsets. On each component k of the DQM attractor there is a unique probability invariant measure k: P_k k. The density of k is positive on the interior of k by the definition of DQM. Any stationary state on M is a convex combination of stationary states k on k.

Let G be shift map along the phase trajectories of (1) during the lag time of DQM.

Definition 4. For the DQM trajectoryfor the time $t_n: y_0, y_1, ..., y_n$ its differential is $D_n()$ $DG(y_n) ... DG(y_1) DG(y_0)$ where $DG(y_k)$ is the differential of G at the point y_k, k n 0,1, For the DQM trajectory : $y_n, ..., y_1, y_0$ differential $D_n()$ $DG(y_n) ... DG(y_1) DG(y_0)$ at n 0,1, The measure G, induced by the measure in accordance with the Kolmogorov theorem [13], is defined on the space of DQM trajectories on the component of the DQM attractor.

Theorem 2. Let M is a component of the DQM attractor of dimension $m \quad \dim M$. Then DQM with sufficiently small $d \min d(y)$ (where d(y) 0 are constants from (3))

1. for almost all under measure DQM trajectories at any nonzero vector $u R^m (u \mid 1)$ there are limits

$$\lim_{n}\frac{1}{n}\ln \|D_{n}\left(\ \right)u\| \qquad r\,,$$
 where $r=1,2,...,s=m$ dim M .

for

2. At each point of each such trajectory, the filtering of subspaces is uniquely defined:

forward
$$L(y)$$
 $L(y)$... $L(y)$ R^m and back $L(y)$... $L(y)$ $L(y)$ R^m ,

associated with the numbers 12... s so that

$$\lim_{n} \frac{1}{n} \ln \|D_{n}(\cdot)u\| \qquad \qquad u \quad L(y) \text{ and } u \quad L(y),$$

$$\lim_{n} \frac{1}{n} \ln \|D_{n}(\cdot)u\| u \quad L \quad \qquad (y) \text{ and } u \quad L_{n}(y).$$

These filtrations are invariant with respect to the DQM differential. Exactly if y_n and y_{n-1} are consecutive points of the trajectoryat times t_n and t_n 1 respectively then the differential $DG(y_n)$ translates the filtering at the point y_n in the filtering at the point y_{n-1} .

Proof. Consider DQM on as a random process X(t,), where t is discrete time, $t t_k$, k 0, 1, 2,..., is a DQM trajectory. Namely, for k M let $\mathbf{\eta} =$

$$(...,\ _k\,,\!...,\ _1\,,\ _0\,,\ _1\,,\!...,\ _k\,,\!...)$$
 . Then the DQM trajectory $(t,y_0\,)$ with an

initial point
$$y_0$$
 M is the sequence $X\left(t_0\,,\,\right)$ $y_0\,,\,X\left(t_1\,,\,\right)$ y_1 $Gy_{00}\,,$

$$X(t_2,)$$
 y_2 $Gy_{11},$..., $X(t_k,)$ y_k $Gy_{k-1k-1},$ (Here d is assumed to be so small that the addition of Gy_{k-1} k 1 when k d performed

on the local map of the manifold M in \mathbb{R}^m). Thus, the DQM trajectory is

defined uniquely by a sequence of vectors $\mathbf{\eta}$ and an initial point y_0 : (y_0 , $\mathbf{\eta}_0$).

On the set of DQM trajectories $X(t, \cdot)$ on induces the dynamic process T – the trajectory of the trajectories: T 01 , T 1 2 , ..., T k 1k , ...

Namely if $(y_0, \mathbf{\eta_0})$, where $y_0 = X(t_0, 0)$, $\mathbf{\eta_0} (..., k, ..., 1, 0, 1, ..., k, ...)$

=R η_{k-1} . By the Kolmogorov theorem on the set of DQM trajectories on the probability measure \overline{w} as determined, induced there by a stationary state on .

By construction measure - inherit from measure the invariance with respect to T (

(T)) and ergodicity of T (i.e. its metric transitivity) under measure . -

Let a(n,) D_n () for (y_0 , $\mathbf{\eta}$). Then a(n,) are measurable functions on a probability space with measure and $a(n \ k,)$ $a(k, T^k)$.

This means that the square matrices $a(n, \cdot)$ of order m are a multiplicative cocycle on the space of trajectories with respect to its automorphism T by the definition of the cocycle [11]. Since G is a diffeomorphism, then $\|DG(y)\| = 0$ for all y, whence $\|DG(y)\| = 0$ is continuous function on compact and $\|DG(y)\| = 0$. On the other hand by definition a measure for any open

subset *C* with the characteristic function *c*

$$_{C}\,d(\{(\overline{y},\)\overline{y}\ C\})=\ (\{yy\ C\})=_{C}d\ .\,\big|$$

Therefore for any piecewise continuous function g on M g d = g d. In particular since a(0,) DG(y) on each trajectory (y, η) , then

$$\ln |a(0, \cdot)| d = \ln |DG(y)| d$$
. This inequality means that the cocycle

 $a(n, \cdot)$ is Lyapunov and this is the condition under which the multiplicative ergodic theorem for this cocycle holds.

This theorem asserts that almost all trajectories under measure are Lyapunov correct. This means, in particular, that

1. for such with $u = R^m (u = 1)$ there are limits

$$\lim_{n \to \infty} \frac{1}{n} \ln \|a(n, \cdot)u\| \qquad (\cdot),$$

where r = 1, 2, ..., s = s() = m.

2. On each such trajectory , the filtering of subspaces is uniquely defined:

forward
$$L(y)$$
 $L(y)$... $L(y)$ R^m and back $L(y)$... $L(y)$ $L(y)$ $L(y)$ R^m ,

associated with the numbers 12...s (s s()) so that

$$\lim_{n} \frac{1}{n} \ln |a(n, u)| \qquad u \quad L(y) \text{ and } u \quad L \qquad (y),$$

$$\lim_{n} \frac{1}{n} \ln |a(n, u)| u L(y) \text{ and } u L$$

These filtrations are invariant with respect to the automorphism T: if T_{nn} 1, then the cocycle $a(n, \cdot)$ takes the filtration n to the filtration n 1.

Since by the Kolmogorov theorem flow T on a probability space with a measure inherits ergodicity from ergodicity P onwith a measure , which was established in Theorem 1. Then the values of r() r, s() s coincide for almost all DQM trajectories under measure . In view of the correspondence a(n,) D_n () the theorem immediately follows from here, QED.

By analogy with the theory of smooth dynamical systems the numbers $_r$ we will call the Lyapunov characteristic exponents of the component of the DQM attractor.

3 Structural Stability in DQM

Definition 5. The DQM realization is a sequence of smooth mappings $G_k(y)$ on in M(k0, 1, 2,...) if $G_k(y)G(y)|_{C_1}d(y)d$, where d(y) are the constants from (3).

Here all the maps $G_k(y)$ are diffeomorphisms on Λ in Λ for sufficiently small d. In terms of content $(t_k, y) = G_k(y)$ G(y) are small random deviations caused by "white noise" at the point y at time t_k . By definition, any DQM trajectory $(y_0, \mathbf{\eta})$: y_k Gy_{k-1} k (k-0, 1, 2,...) is given by the initial point y_0M and sequence of deviations $\mathbf{\eta}$ (..., k,..., 1, 0, 1,..., k,...). But on

the DQM realization the function of deviations (t_k, y) is fixed; therefore, on it the DQM trajectory with the initial point y_0 is uniquely determined: (y_0).

Definition 6. A DQM realization $G_k(y)$ (k = 0, 1, 2,...) on a compact set will be called a hyperbolic realization of DQM if at each point $y K_k$, K where K_0 K_0 K_0 K_k K_k K_k there exists a decomposition of the tangent bundle TK_k into the Whitney sum of the subbundles $E_k^s(y)$ and $E_k^u(y)$: $TK_k = E_k^s(y)$ + $E_k^u(y)$, satisfying the following conditions:

1. the tangent map DG_k preserves the subbundles:

$$DG(E^s)$$
 E^s , $DG(E^u)$ E^u

 $DG(E^s)$ E^s , $DG(E^u)$ E^u ; DG compresses E^s : on every trajectory with an initial point y Ktime moment t_k there are such constants b 0 and (01) that for any $u E_k^s$ and any natural n

$$D_n()u \|b^n\|u\| (u E_k^s(y)).$$

DG stretches $E^{u}\left(y\right)$, more precisely, on each trajectorywith an initial point $_{^{k}}$ y K_k at the time moment t_k for any $u E_k^u$ and a natural n

$$|D_n(u)u|| \frac{1}{h^n} |u|| (u E_k^u(y)).$$

Theorem 3. Hyperbolic realizations are everywhere dense on the set of DQM realizations. More precisely, for any DQM realization G_k (y) (k 0, 1, 2,...) and

for any sufficiently small 0 there exists such hyperbolic realization $G_k(y)$ of this DQM on the compact K, that

(/K/K/) for the probabilistic invariant DQM measure on;

2. on
$$K_k = G_k(y) G_k(y) |_{C_1(k = 0, 1, 2,...)}$$

Definition 7. The realization of the DQM $G_k(x)$ on a compact K and the realization $G_k(x)$ of this DQM on a compact Kare topologically equivalent if they are conjugate by means of homeomorphisms H_k defined on some neighborhoods

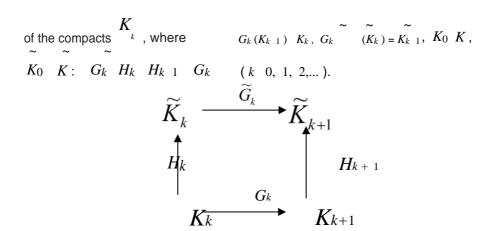

Fig. 1. Commutative diagram of topological equivalence.

Definition 8. A DQM realization $G_k(x)$ on a compact K is structurally stable if any realization of this DQM sufficiently close to $G_k(x)$ in C^1 topology for all k = 0, 1, 2,... is topologically equivalent to it.

In more detail: If for every point x K_k there are numbers $d_k(x)$ 0 such that for any realization of this DQM $G_k(x)$ from $\|G_k(x)G_k(x)\|_{C^1} \le d_k(x)$ for all k

and x K_k the topological equivalence of the realizations G_k and G_k follows, then G_k is structurally stable.

If all $G_k(x)$ and all compacts K_k coincide for all k, then we obtain the definition of the structural stability of a diffeomorphism.

Theorem 4. Any hyperbolic realization of the DQM G_k on the compact set K is structurally stable.

Corollary 1. A diffeomorphism G on a compact manifold M is structurally stable in the sense of Definition 8 if and only if it is (non-uniformly) hyperbolic. **Proof.** Let a diffeomorphism G be structurally stable. By Definition 8, this means

that for some from G(x) G(x) G(x) it follows

that the diffeomorphisms G and G are topologically equivalent, that is, are conjugate on M by means of a homeomorphism. Consider DQM for G with the same d (x) in (3) for all x M. By Theorem 1, this DQM has an attractor, let be a component

of this attractor. By Theorem 3 there is a realization $G_k(x)$ of this DQM, hyperbolic in the sense of Definition 6 on a compact set K, which differs from only by the order d on the measure of the stationary state on . Then by virtue of the

~

structural stability of G every diffeomorphism G_k of this realization is conjugate to G in a neighborhood of . Therefore the realization with zero deviations, i.e. coinciding with G for each k, is also hyperbolic in in the sense of Definition 6, and the component itself is invariant with respect to G with accuracy . But then the complement $M\setminus$ is invariant with respect to G with accuracy too. Unless it turns out that with this accuracy M, then on $M\setminus$ we can similarly consider DQM for G with perhaps smaller than the earlier d (y) . You can find there its

component $_1$ and establish for realization $\overline{G_k}$ with zero deviations hyperbolicity in neighborhood of in the sense of Definition 6 $_1$ as we did it early; and so on. In general let be the greatest G -invariant with accuracy subset in M, in which the realization with zero deviations $G_k(x)$ is hyperbolic in the sense of Definition 6. If

M with accuracy , then on $M\setminus$ as above we can obtain a new component, in which the realization with zero deviations G_k is hyperbolic contrary to the assumption about . Tending to zero, we obtain the hyperbolicity of the realization \overline{G}_k with zero deviations at almost all points x M. In this case, generally speaking, we have $\inf d(x) = 0$. This means the non-uniform hyperbolicity of the diffeomorphism G onto M.

Conversely, the fact that the non-uniform hyperbolicity of a diffeomorphism $\,G\,$ onto $\,M\,$ implies its structural stability in the sense of Definition 8 directly follows from Theorem 4, QED.

Corollary 2. If for some 0 from G(x) G(x) G(x) G(x) G(x) G(x) follows that diffeomorphisms G and G are topologically equivalent, then G is (uniformly) hyperbolic diffeomorphism on G.

Proof. It follows from Corollary 1 that G is hyperbolic, in general, non-uniform. If G is hyperbolic exactly non-uniformly and so $\inf d(y) = 0$ for d(y) from definition 8, then we can get $\sup_{x \in G} \inf_{x \in G} G(x) = 0$ with arbitrarily small perturbations. However from G(x) = G(x) = 0 ($x \in G(x) = 0$) follows that G and G are topologically equivalent by the condition of the corollary. Therefore G is uniformly hyperbolic on G, QED.

4 Example of DQM Application: Henon System Attractor

For the two-dimensional M. Henon system [10]: (x, y) $(1 \ y \ ax^2, bx)$ values of parameters a 1.7, b 0.5 are chosen such that the hyperbolicity of dynamics on the attractor with this parameters is rigorously proved for R. Lozi system [14] (x, y) $(1 \ y \ a \ x, bx)$ | The proof of the hyperbolic dynamics here is based on

the following statement, specifically focused on the study of concrete dynamical systems. For ease of application to the Henon system in the formulation we restrict ourselves to the two-dimensional case, although the multidimensional generalization is also true.

Corollary 3. Let i be the cells of -discretization of the DQM attractor for the system given by the diffeomorphism G, x_{i} , (1 i N). Let the eigenvalues

$$_{1}\left(x_{i}\right)$$
 and $_{2}\left(x_{i}\right)$ of the differential DG at each point x_{ii} $(1 \ i \ N)$ satisfy the conditions $_{1i}^{(x)}\left(x\right)$ $\frac{1}{_{2}}$ for some (01) and

$$\frac{(1)^2}{4(4\|G\|_2-1)} \tag{6}$$

where $\|G\|_2$ is the norm of G in $\|C\|^2$. Then

- 1. the initial system given by the diffeomorphism G is hyperbolic on its attractor;
- 2. any DQM realization of this system is hyperbolic on the DQM attractor and is topologically equivalent to the initial system;
- 3. the support of the attractor of the initial hyperbolic system and the attractor of its DQM realization coincide with an accuracy of order .

The proof of this statement essentially reproduces the proof of Theorem 4, estimate (6) is actually obtained there. The verification of the conditions of Corollary 3 for the Henon system uses 4 *Maple* procedures.

1. The *Animate* procedure visualizes system behavior using animation technologies in *Maple*. This allows you to localize the region of the phase space in which the system attractor is hypothetically contained. In the graph of next fig.2 for each iteration *t* shows the point in phase space of Henon system.

On the basis of outcomes of the numerical researches, visually presented in Figure 2, we choose a rectangle $\{(x,y) \mid 1 \ x \ 1.5; \ 0.1 \ y \ 0.1\}$. In next Figure 3 for each iteration $t \ 1,2,...,500$ of Henon system corresponds its coordinate x(t) on the ordinate axis.

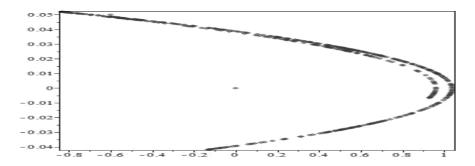

Fig. 2. Phase curve of Henon system.

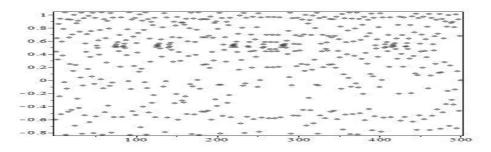

Fig. 3. Trajectory of Henon system.

The animation in Figure 3 suggests that the system is hyperbolic.

- 2. The *Prestep* procedure splits the rectangle into cells i squares with sides of length 0.01 parallel to the axes of coordinates (1 i N). Then each cell i *Prestep* associates a set of cells into which points from i can fall into one step of the dynamics of the Henon system. In this case it is formally verified that the domain is indeed invariant with respect to the discretization of the DQM, given by the constructed partition of . In other words *Prestep* defines a topological Markov chain H, the state space of which is the set of cells i.
- 3. The *Findattr* procedure finds in the attractor of a topological Markov chain H defined in *Prestep*. Its algorithm is based on the following consideration. On the state space $\{i\}$ consider a transitive quasi-order relation: ij if there exists a trajectory H from i to j. The state i is recurrent if ii. Recurrent states are divided into equivalence classes: $i \sim jiji$.

On
$$\{$$
 $i\}$ $H($ $)$ $H_2($ $)$ $H_3($ $)$... $H_n($ $)$. If $H_n($ $)$ $H^{n-1}($ $)$ then $H^n($ $)$ is the DQM attractor. In the case under consideration, the

attractor turns out to be connected, which corresponds to Fig. 2, obtained by the *Animate* procedure.

4. The *Hyperproc* procedure performs a main check: do the conditions of Corollary 3 be satisfied on the attractor found by *Findattr*? For the Henon system under consideration on a rectangle $\{(x, y) \mid 1 \mid x \mid 1.5; 0.1 \mid y \mid 0.1\}$ we obtain $\|G\|_2 \max\{ \sqrt{(2ax)^2 \mid b^2 \mid 1, 2a} \}$ 6.1. The *Hyperproc* procedure establishes that for the differential DG eigenvalues $_1(x_i)$ 0.4 and $_2(x_i)$ 1.7 for all x_i 1. The value $_1/1,7$ 0.59. Thus 0.59; however, we choose the value 0.7 with a margin. Then, in accordance with (6), it is necessary that 0.00089.

Now the cell length of i (the length of a square with sides parallel to the axes of coordinates) is chosen equal to 0.0005 (1 i N) and already for such a small partition of the rectangle we repeat the *Prestep Findattr Hyperproc* cycle described above. Now the other smaller cells are i, the other x_i and the other eigenvalues 1 (x_i) and 2 (x_i) respectively (1 i N). If now again 1 (x_i) 0.4 and 2 (x_i) 1.7 holds for all i, then (6) holds for such a partition and therefore Corollary 3 holds. In our case, the test was successful, which proves the hyperbolicity of the dynamics on the attractor of the Henon system for the values of the parameters a 1.7, b 0.5. As a result, the structure of a topological Markov chain obtained in the course of computer calculations, by virtue of 2) and 3) of Corollary 3, gives detailed and rigorously proved data on the dynamics of this system.

The selected values of the parameters a 1.7, b 0.5 are not the only ones. For example, similar results are obtained for a 1.4, b 0.35.

5 Conclusion

The structural stability of a mathematical model is a necessary condition for its correctness. It is also necessary for applicability of numerical methods, computational experiments since they inevitably lead to errors.

But after S. Smale's works it became clear that in smooth dynamics the system of a general form is not structurally stable and therefore there is no strict mathematical basis for modeling and computational analysis of systems. The contradiction appeared in science: according to physicists dynamics is simple and universal.

The paper proposes a solution to this problem based on the construction of dynamic quantum models (DQM). DQM is a perturbation of a smooth dynamical system by a Markov cascade (time is discrete). The dynamics obtained in this way are simpler than the classical smooth dynamics: the structurally stable realizations of DQM are everywhere dense (Theorem 3) and open (Theorem 4) on the set of all DQM realizations. This dynamics has a clear structural theory: unlike the classical systems, the DQM attractor is uniquely defined (Theorem 1), Lyapunov exponents exist for any DQM (Theorem 2).

As a Markov cascade, the DQM is approximated by a Markov chain and on a compact set by a finite Markov chain arbitrarily exactly (Theorem 1). This allows you to clearly understand the DQM dynamics and build effective algorithms for the study of concrete systems that are always oriented towards parallel computing and do not require stable (according to Hadamard) solutions. For example, in part 4 we demonstrate the use of computer simulation for rigorous proof of hyperbolicity of the attractor of Henon system.

On the other hand, when fluctuations tend to zero, i.e. in the semiclassical limit, the dynamics of the DQM goes into the initial smooth dynamics. In part 3 the equivalence of structural stability and hyperbolicity for smooth discrete dynamical systems is established along this path (Corollaries 1 and 2).

In the future, we intend to apply the DQM algorithms, that oriented towards parallel computing and do not require stable solutions, to traditional problems of computational methods.

We also intend to generalize dynamic quantum models on dynamical systems that using logical operations: proofs of theorems, software applications, information and network systems, etc. A natural and even obvious implementation tools for such a generalization are the specialized neural network. This will allow the use of DQM methods for problems of artificial intelligence: identification, prediction, filtering, etc.
